

Error growth on intra-daily timescales

The importance of the daily cycle in variability

**Åke Johansson
SMHI**

Error growth

In chaotic systems the uncertainty in a forecast increases *exponentially* with time.

However, the uncertainty can not grow for ever and have an upper limit which is equal to the difference between two random states.

Lorenz proposed as a prototype error growth model a logistic curve

$$y = \frac{e^t}{e^t + 1}$$

which has been found very appropriate for NWP.

Logistic equation error growth

Two parameters

- **Growth rate**
- **Initial error**

Real NWP error growth

Hypothesis

The error at the verification time is scaled by the climatological variance at this specific point in the

- Yearly cycle
- Daily cycle

The saturation value varies with

- **Time of year**
- **Time of day**

Variability in the Atmosphere

- Yearly Cycle
- Daily Cycle
- "Weather"

Length of a Year

Tropical year	365.24219 days
Anomalistic year	365.25964 days

Conclusions

- The error magnitude at the verification time is critically dependent on the climatological variance at the **time of day** and **time of year**
- To make errors comparable they have to be normalized by appropriately defined climatological variances
- Therefore **VARIANCE(stn,variable,day,hour)** has to be calculated and used in the verification
