## 24 **SI1: Eulerian versus residual mean overturning stream function**

25 The residual mean mass overturning stream function ( $\Psi_r$ , in  $kg/s$ ) is the diagnostic variable rec-  
26 ommended by the Ocean Model Intercomparison Project (OMIP) endorsed in the Coupled Model  
27 Intercomparison Project Phase 6 (CMIP6) exercise (Griffies et al. 2016). It includes, in addition  
28 to the Eulerian mean mass transport in the meridional plane, the eddy-induced mass transport  
29 from parametrized subgrid-scale processes, namely the Gent and McWilliams (1990) mesoscale  
30 parametrization and the Fox-Kemper et al. (2008) submesoscale parametrization in the CNRM-  
31 CM6 climate model (Voldoire et al. 2019). Those mass transports quantify the contribution of  
32 eddy fluxes to tracer advection and are as such associated with no Eulerian mean volume trans-  
33 port. They are hardly measurable and in particular they are not included in the long-term RAPID  
34 section of the AMOC at  $26.5^\circ N$ . They are not directly related to the Eulerian mean Ekman and  
35 geostrophic transports, making any physical decomposition of AMOC more challenging.

36 As a consequence, we have used the Eulerian mean overturning stream function, which only  
37 includes the Eulerian mean volume transport resolved by CNRM-CM6 model and can be com-  
38 puted from the model's meridional velocities. Hence it is comparable to RAPID measurements  
39 and it formally relates to the thermal wind relation in the geostrophic approximation, which is a  
40 requirement of our AMOC physical decomposition. We evaluate here the difference between both  
41 AMOC definitions. Overall, the Eulerian mean ( $\Psi$ , Fig.1a) overturning stream function is weaker  
42 than its residual mean counterpart ( $\Psi_r/\rho_0$  with  $\rho_0 = 1025kg/m^3$ , Fig.SI1a) by a few Sverdrups  
43 over the AMOC cell of the Atlantic ocean (Fig.1). This is confirmed by the mean AMOC (Fig.1b)  
44 which is increased by 11 to 25% south of  $60^\circ N$  when including the eddy-induced transport. At the  
45 latitude of the RAPID array, it is increased by 14%, whereas at the latitudes of the OSNAP section  
46 ( $52 - 60^\circ N$ , Lozier et al. (2017)) it is increased by 18%. However, both AMOC definitions have  
47 an interannual correlation above 0.95 south of  $60^\circ N$ , thus indicating that the AMOC variability is

48 mostly not eddy-driven. We conclude that the mean AMOC significantly differs in CNRM-CM6  
49 when computed as a residual mean transport, which biases model evaluation against observations,  
50 but that its interannual variability remains unchanged.

## 51 **SI2: Depth versus density coordinate AMOC**

52 In our study, we establish a simple diagnostic relation between the depth coordinate AMOC  
53 (hereafter  $AMOC_z$ ) variability and density anomalies at zonal boundaries of the Atlantic Ocean.  
54 We show here that because of a zonally-varying interface depth, no such simple relation exists for  
55 the density coordinate AMOC (hereafter  $AMOC_\sigma$ ). We first recall the main differences between  
56 both AMOC definitions. The overturning circulation of the Atlantic ocean has historically been  
57 quantified with  $AMOC_z$  (e.g. the RAPID array). It is a Eulerian transport, and as such it is easily  
58 calculated from the zonal section of meridional velocities. It dominates the northward oceanic heat  
59 transport outside of subpolar latitudes (McCarthy et al. 2015). However, over the past two decades,  
60  $AMOC_\sigma$  has been extensively used for studies of the subpolar North Atlantic (e.g. OVIDE and  
61 OSNAP arrays, Mercier et al. (2015); Lozier et al. (2019)). It is a residual mean transport because it  
62 depends on zonal co-variations of meridional velocities and the interface depth between the upper  
63 and lower AMOC limbs, which is an isopycnal. Therefore, it is more challenging to calculate as it  
64 should be computed online at the model time step frequency in numerical simulations. However, it  
65 dominates the northward oceanic heat transport at all latitudes of the Atlantic Ocean and it relates  
66 naturally to water mass transformations in density space.

67 Let us illustrate the main dynamical difference between  $AMOC_z$  and  $AMOC_\sigma$  in the rectangular  
68 basin case. The AMOC transport is:

$$AMOC = \int_{x_W}^{x_E} \int_d^0 v dz dx$$

69 with  $d$  either the constant depth  $z_m$  of maximum overturning for  $AMOC_z$  or the zonally-variable  
70 isopycnal depth  $d_m$  (corresponding to the density  $\sigma_m$  of maximum overturning) for  $AMOC_\sigma$ . Its  
71 geostrophic component can be expressed as an integral zonal pressure force exerted by the volume  
72 of fluid at its boundaries:

$$\begin{aligned}
 AMOC_g &= \int_{x_W}^{x_E} \int_d^0 v_g(x, y, z, t) dz dx \\
 &= \frac{1}{\rho_0 f} \int_{x_W}^{x_E} \int_d^0 \frac{\partial P}{\partial x} dz dx
 \end{aligned}$$

73 with  $x_W$  and  $x_E$  the western and eastern boundaries,  $v_g$  the meridional geostrophic velocity and  $P$   
74 the pressure. Leibniz integration formula allows to write this pressure gradient as an interior plus  
75 an interfacial pressure force:

$$\begin{aligned}
 AMOC_g &= \frac{1}{\rho_0 f} \int_{x_W}^{x_E} \left( \frac{\partial}{\partial x} \int_d^0 P dz + P(d) \frac{\partial d}{\partial x} \right) dx \\
 &= \frac{1}{\rho_0 f} \left( \int_{d(x_E)}^0 P(x_E, z) dz - \int_{d(x_W)}^0 P(x_W, z) dz + \int_{x_W}^{x_E} P(d) \frac{\partial d}{\partial x} dx \right) \\
 &= \frac{1}{\rho_0 f} \left( \Delta \left( \int_d^0 P dz \right) + \overline{\Delta x P(d) \frac{\partial d}{\partial x}} \right)
 \end{aligned}$$

76 with  $\Delta x = x_E - x_W$  the basin zonal width,  $\Delta(A(x)) = A(x_E) - A(x_W)$  for any function  $A(x)$  and  
77 the overline denoting a zonal average. The first term represents the pressure force exerted by the  
78 volume of fluid onto the solid Earth at the lateral boundaries, and will be referred to as the "lateral  
79 pressure force". In the general case of a sloping bottom, this term becomes a bottom form stress  
80 exerted onto topography above the depth  $z_m$ . The second term is the so-called "interfacial form  
81 stress", which represents the zonal pressure force exerted at the interface  $d$  onto the underlying  
82 fluid.

83 We now replace the lower depth  $d$  by the depth  $z_m$  of maximum meridional overturning in vertical  
84 coordinate and the depth  $d_m = d(\sigma = \sigma_m)$  with  $\sigma_m$  the density of maximum meridional overturn-  
85 ing in density coordinate, respectively. We obtain the respective expressions for the geostrophic

86 component of the  $AMOC$  in depth and density coordinates:

$$\begin{aligned}
 AMOC_{zg} &= \frac{1}{\rho_0 f} \int_{z_m}^0 \Delta P dz \\
 AMOC_{\sigma g} &= \frac{1}{\rho_0 f} \left( \Delta \left( \int_{d_m}^0 P dz \right) + \overline{\Delta x P(d_m) \frac{\partial d_m}{\partial x}} \right)
 \end{aligned}$$

87 It appears clearly that the main difference between both formulations of the  $AMOC$  is that the in-  
 88 terfacial form stress is a source of net meridional transport for the  $AMOC_{\sigma}$  and not for the  $AMOC_z$ .  
 89 Indeed, because of a slanted lower boundary  $d_m$ , a net zonal pressure force can be exerted onto  
 90 the lower fluid. As a consequence of the geostrophic balance, this interfacial form stress induces a  
 91 net meridional geostrophic flow above the depth  $d_m$ . This latter term depends on the zonal profile  
 92 of pressure at the interface, which is a function of the full zonal density section and dynamic sea  
 93 level profile, and of the zonal profile of the isopycnal interface depth. As a consequence, no simple  
 94 relation can be derived between  $AMOC_{\sigma}$  and hydrographic properties at zonal boundaries. This  
 95 is why  $AMOC_{\sigma}$  has been discarded from our dynamical analysis, although we acknowledge its  
 96 relevance for the study of meridional heat transports and water mass transformations (e.g. Mercier  
 97 et al. (2015); Lozier et al. (2019)).

### 98 **SI3: How the density anomaly profile controls the maximum overturning depth and the** 99 **thermal wind transport**

#### 100 *Determination of the maximum overturning depth*

101 In section 2e, we have established the depth dependency of the thermal wind transport  $TW(z)$   
 102 and concluded that a given density anomaly induces most  $AMOC_{g-sh}$  transport if it occurs at the  
 103 depth  $z_m$  of maximum overturning. However, our diagnostic relation for a given depth  $z_m$  does  
 104 not predict what controls that depth. If we only consider the vertically-compensated geostrophic  
 105  $AMOC_{g-sh}$  transport, that depth is a function of the full vertical profile of density times either

106 depth, or height above bottom. Indeed, the derivative of  $AMOC_{g-sh}$  as a function of  $z_m$  is:

$$\begin{aligned} \frac{\partial AMOC_{g-sh}}{\partial z_m} &= \frac{g}{\rho_0 f} \left( \int_{-h}^{z_m} \left(1 + \frac{z'}{h}\right) \Delta\rho dz' + z_m \left(1 + \frac{z_m}{h}\right) \Delta\rho - z_m \Delta\rho + \int_{z_m}^0 \frac{z'}{h} \Delta\rho dz' - z_m \frac{z_m}{h} \Delta\rho \right) \\ &= \frac{g}{\rho_0 f} \left( \int_{-h}^{z_m} \left(1 + \frac{z'}{h}\right) \Delta\rho dz' + \int_{z_m}^0 \frac{z'}{h} \Delta\rho dz' \right) \end{aligned}$$

107 where we have applied the formulas for the derivatives of a product and of an integral. The first  
 108 term is the transport increase due to the increasing thickness of the upper limb, which is fully  
 109 impacted by density anomalies occurring below  $z_m$ . The second term is the transport reduction  
 110 due to the increasing barotropic compensation of baroclinic transports driven by densities above  
 111  $z_m$ . Near surface, the first term is larger so that the transport increases with depth. Near the  
 112 bottom, the second term is larger so that the transport decreases with depth. In between, the depth  
 113 of maximum overturning is reached when both terms are equal and opposite in sign, meaning that  
 114 the transport reduction due to the upper limb densities exactly compensates the transport increase  
 115 due to lower limb densities. Mathematically, it is :

$$\begin{aligned} \frac{\partial AMOC_{g-sh}}{\partial z_m} &= 0 \\ \implies \int_{-h}^{z_m} \left(1 + \frac{z'}{h}\right) \Delta\rho dz' &= \int_{z_m}^0 \frac{-z'}{h} \Delta\rho dz' \end{aligned}$$

116 This relation shows that the depth  $z_m$  depends crucially on the density anomaly profile. Qualita-  
 117 tively, the larger the near-surface density anomalies, the shallower the maximum overturning and  
 118 the shallower the density anomalies that induce most upper limb transport. In the particular case

119 of a constant density anomaly at all depths, we obtain :

$$\begin{aligned}
& \frac{\partial AMOC_{g-sh}}{\partial z_m} = 0 \\
\implies & \left[ z' + \frac{z'^2}{2h} \right]_{-h}^{z_m} + \left[ \frac{z'^2}{2h} \right]_{z_m}^0 = 0 \\
& \implies z_m + h - \frac{h}{2} = 0 \\
& \implies z_m = -\frac{h}{2}
\end{aligned}$$

120 that is, a maximum overturning at mid-depth  $\frac{h}{2}$ , and therefore a maximum thermal wind transport  
121  $TW(z)$  induced by density anomalies at that depth.

122 We illustrate the dependency of the maximum overturning depth on the density anomaly profile  
123 with Fig. SI2. Two vertically-symmetric profiles are shown with density anomalies located either  
124 near the surface (left) or near the bottom (right). In the former case (left), the near-surface negative  
125 density anomaly induces a positive (Northern Hemisphere) vertical shear of geostrophic velocities.  
126 By mass conservation the vertical mean sheared velocity must cancel out, hence positive velocities  
127 from the surface to near the base of the density anomaly, and negative velocities below. As a  
128 consequence, the associated stream function increases from surface to the depth where sheared  
129 velocities go to zero, and then decreases down to the bottom. The resulting depth  $z_m$  of maximum  
130 overturning is close to the surface, near the basis of the density anomalies. Symmetrically, in the  
131 latter case (right), near-bottom density anomalies cause a vertical shear of geostrophic velocities  
132 and as a result of mass conservation, positive velocities from surface to near the top of the density  
133 anomalies, and then negative anomalies below. The associated overturning stream function reaches  
134 a maximum at a depth  $z_m$  near the bottom, next to the top of density anomalies.

135 *Determination of the maximum thermal wind transport*

136 We have shown that the density anomaly profile plays a key role in determining the depth of  
137 maximum overturning. Here we illustrate how this depth of maximum overturning, together with  
138 the density anomaly profile, controls the thermal wind transport  $TW$ . We recall that this thermal  
139 wind transport, in  $Sv/m$ , quantifies the contribution of density anomalies at a given depth to the  
140 sheared geostrophic transport above  $z_m$ , so that its vertical integral is the value of the overturn-  
141 ing stream function at  $z_m$ . Fig. SI2 shows that the thermal wind transport is only positive at the  
142 depth where density anomalies occur, and that for a given density anomaly, the closer to the max-  
143 imum overturning depth  $z_m$ , the larger  $TW$ . As a consequence,  $TW$  is maximum near the basis of  
144 the surface-intensified density anomalies (left), and near the top of the bottom-intensified density  
145 anomalies (right). For a given density anomaly,  $TW$  decreases linearly towards the surface and  
146 bottom, to cancel out at both boundaries.

147 Fig. SI3 illustrates how for a given  $z_m$ , the magnitude of the thermal wind transport is propor-  
148 tional to that of density anomalies. In both examples, density anomalies are located at mid-depth,  
149 so that geostrophic velocities change sign at that depth and the resulting depth of maximum over-  
150 turning is  $z_m = -h/2$ . The only difference is the doubling of the magnitude of density anomalies  
151 in the second case (right) compared to the first one (left). As a result, sheared velocities and their  
152 overturning stream function are also doubled, as well as  $TW(z)$  at the depths where density anoma-  
153 lies occur. The maximum overturning, which is by definition the vertical integral of the thermal  
154 wind transport, is therefore also doubled in the latter case.

155 **SI4: Geostrophic AMOC computation with variable bathymetry**

156 Let us first consider a zonal section with strictly increasing topography on both sides of the  
 157 deepest bathymetry  $-h_b$ . In this case, the baroclinic geostrophic transport of AMOC is insensitive  
 158 to topographic details. The only requirement is to consider at each depth the easternmost and  
 159 westernmost densities for the computation of the baroclinic geostrophic AMOC transport. Indeed,  
 160 we have:

$$\begin{aligned}
 AMOC_{BCg} &= -\frac{g}{\rho_0 f} \int_{z_m}^0 \int_{x_W(z)}^{x_E(z)} \int_{-h(x)}^z \frac{\partial \rho}{\partial x}(z') dz' dx dz \\
 &= -\frac{g}{\rho_0 f} \int_{x_W(0)}^{x_E(0)} \int_{\max(-h, z_m)}^0 \int_{-h(x)}^z \frac{\partial \rho}{\partial x}(z') dz' dz dx \\
 &= -\frac{g}{\rho_0 f} \int_{x_W(0)}^{x_E(0)} \int_{\max(-h, z_m)}^0 \left( \int_{-h(x)}^{\max(-h, z_m)} \frac{\partial \rho}{\partial x}(z') dz' + \int_{\max(-h, z_m)}^z \frac{\partial \rho}{\partial x}(z') dz' \right) dz dx \\
 &= +\frac{g}{\rho_0 f} \int_{x_W(0)}^{x_E(0)} \left( \int_{-h(x)}^{\max(-h, z_m)} \max(-h, z_m) \frac{\partial \rho}{\partial x} dz' + \int_{\max(-h, z_m)}^0 z' \frac{\partial \rho}{\partial x} dz' \right) dx \\
 &= +\frac{g}{\rho_0 f} \left( \int_{x_W(z_m)}^{x_E(z_m)} \int_{-h(x)}^{z_m} z_m \frac{\partial \rho}{\partial x} dz' dx + \int_{x_W(0)}^{x_E(0)} \int_{\max(-h, z_m)}^0 z' \frac{\partial \rho}{\partial x} dz' dx \right)
 \end{aligned}$$

161 where we have used the double integration rule. In the last step, we have noted that the first  
 162 integral vanishes when  $h < -z_m$ , so that integrals between  $x_W(0)$  and  $x_W(z_m)$  and between  $x_E(0)$   
 163 and  $x_E(z_m)$  vanish and  $\max(-h, z_m) = z_m$  between  $x_W(z_m)$  and  $x_E(z_m)$ , since  $h > -z_m$ . Finally,  
 164 reversing the order of integration and integrating zonally yields:

$$\begin{aligned}
 AMOC_{BCg} &= +\frac{g}{\rho_0 f} \left( \int_{-h_b}^{z_m} \int_{x_W(z)}^{x_E(z)} z_m \frac{\partial \rho}{\partial x} dx dz + \int_{z_m}^0 \int_{x_W(z)}^{x_E(z)} z \frac{\partial \rho}{\partial x} dx dz \right) \\
 &= +\frac{z_m g}{\rho_0 f} \int_{-h_b}^{z_m} \left( \rho(x_E(z), z) - \rho(x_W(z), z) \right) dz + \frac{g}{\rho_0 f} \int_{z_m}^0 z \left( \rho(x_E(z), z) - \rho(x_W(z), z) \right) dz \\
 &= +\frac{z_m g}{\rho_0 f} \int_{-h_b}^{z_m} \Delta \rho(z) dz + \frac{g}{\rho_0 f} \int_{z_m}^0 z \Delta \rho(z) dz
 \end{aligned}$$

165 with  $\Delta \rho(z) = \left( \rho(x_E(z), z) - \rho(x_W(z), z) \right)$ . The reversal of vertical and zonal integrals is allowed  
 166 by the assumption of a strictly monotonic bathymetry on both sides of  $h_b$ , which is the mathematical

167 translation of the neglect of ridges and islands. The above expression is identical to the rectangular  
 168 basin case, but we evaluate the boundary density at the westernmost and easternmost location of  
 169 each depth, and we integrate the thermal wind relation from the deepest bathymetry  $h_b$ .

170 The section-integrated meridional transport becomes:

$$\begin{aligned}
 \Psi(-h_b) &= AMOC_E + \int_{-h_b}^0 \int_{x_W(z)}^{x_E(z)} \left( v_g(-h) - \frac{g}{\rho_0 f} \int_{-h(x)}^z \frac{\partial \rho}{\partial x}(z') dz' \right) dx dz \\
 &= AMOC_E + \int_{x_W(0)}^{x_E(0)} \int_{-h(x)}^0 \left( v_g(-h) - \frac{g}{\rho_0 f} \int_{-h(x)}^z \frac{\partial \rho}{\partial x}(z') dz' \right) dz dx \\
 &= AMOC_E + \int_{x_W(0)}^{x_E(0)} \left( h(x) v_g(-h) - \frac{g}{\rho_0 f} \int_{-h(x)}^0 \int_{z'}^0 \frac{\partial \rho}{\partial x}(z') dz dz' \right) dx \\
 &= AMOC_E + \Delta x(0) \overline{h v_g(-h)} + \frac{g}{\rho_0 f} \int_{x_W(0)}^{x_E(0)} \int_{-h(x)}^0 z' \frac{\partial \rho}{\partial x}(z') dz' dx \\
 &= AMOC_E + \Delta x(0) \left( \overline{h v_g(-h)} + \overline{h' v_g(-h)'} \right) + \frac{g}{\rho_0 f} \int_{-h_b}^0 z \Delta \rho(z) dz
 \end{aligned}$$

171 where  $\Delta x(0) = x_E(0) - x_W(0)$  and the overline and prime denote a zonal mean and anomaly. We  
 172 have simplified the double vertical integral and reversed zonal and vertical integral similarly as for  
 173  $AMOC_{BCg}$ . The term involving zonal anomalies is part of the so-called "external mode", which is  
 174 the only explicit dependency to the reference vertical level chosen for the thermal wind integration.  
 175 It can be viewed as a projection of the barotropic (gyre) transport onto the AMOC. We finally get:

$$\begin{aligned}
 \Psi(-h_b) &= 0 \\
 \iff \overline{v_g(-h)} &= -\frac{1}{\overline{h \Delta x(0)}} \left( AMOC_E + \Delta x(0) \overline{h' v_g(-h)'} + \frac{g}{\rho_0 f} \int_{-h_b}^0 z \Delta \rho(z) dz \right)
 \end{aligned}$$

176 which yields the barotropic geostrophic transport of AMOC:

$$\begin{aligned}
AMOC_{BTg} &= \int_{z_m}^0 \int_{x_W(z)}^{x_E(z)} v_g(-h) dx dz \\
&= \int_{x_W(0)}^{x_E(0)} \int_{\max(-h, z_m)}^0 v_g(-h) dz dx \\
&= - \int_{x_W(0)}^{x_E(0)} v_g(-h) \max(-h, z_m) dx \\
&= + \int_{x_W(0)}^{x_E(0)} v_g(-h) \min(h, -z_m) dx \\
&= \Delta x(0) \overline{v_g(-h) \min(h, -z_m)} \\
&= \Delta x(0) \left( \overline{v_g(-h) \min(h, -z_m)} + \overline{\min(h, -z_m)' v_g(-h)'} \right) \\
&= \Delta x(0) \left( - \overline{v_g(-h) \bar{z}_m} + \overline{\min(h, -z_m)' v_g(-h)'} \right)
\end{aligned}$$

177 where  $\bar{z}_m = \overline{-\min(h, -z_m)}$  is the mean depth of the upper limb AMOC zonal section. Finally,

178 expressing  $\overline{v_g(-h)}$  as deduced from the no net meridional flow condition gives:

$$AMOC_{BTg} = + \frac{\bar{z}_m}{\bar{h}} \left( AMOC_E + \frac{g}{\rho_0 f} \int_{-h_b}^0 z \Delta \rho(z) dz \right) + \Delta x(0) \left( \frac{\bar{z}_m}{\bar{h}} \overline{h' v_g(-h)'} + \overline{\min(h, -z_m)' v_g(-h)'} \right)$$

179 Again, it resembles the rectangular basin case. Similarly to  $AMOC_{BCg}$ , the zonal and vertical

180 thermal wind integrations are little modified. We have replaced the factor  $z_m/h$  by its zonal average

181  $\bar{z}_m/\bar{h}$ , which still represents the fraction of the total barotropic transport that is located in the upper

182 AMOC limb. Most importantly, we have added the "external mode" which represents the zonal

183 covariance of  $v_g(-h)$  with bathymetry and the upper limb depth:

$$AMOC_{g-EM} = \Delta x(0) \left( \frac{\bar{z}_m}{\bar{h}} \overline{h' v_g(-h)'} + \overline{\min(h, -z_m)' v_g(-h)'} \right)$$

184 It is generally not null because of the existence of boundary currents that lean on topographic

185 obstacles, and hence non-null covariances between bottom velocity and either bathymetry or the

186 upper limb depth. In section SI5, we show that the external mode can be equivalently expressed

187 as an integral corrected bottom velocity (Baehr et al. 2004) or barotropic velocity (Hirschi and  
 188 Marotzke 2007). Finally, we obtain an almost identical expression for the AMOC as in the rectan-  
 189 gular basin case, with the addition of the "external mode" (equation 19):

$$\begin{aligned}
 AMOC = & -\left(1 + \frac{\bar{z}_m}{h}\right) \frac{\Delta x(0)}{\rho_0 f} \bar{\tau}_x + \frac{g}{\rho_0 f} \left( \int_{-h_b}^{z_m} \left(z_m + \frac{\bar{z}_m}{h} z\right) \Delta \rho(z) dz + \int_{z_m}^0 z \left(1 + \frac{\bar{z}_m}{h}\right) \Delta \rho(z) dz \right) \\
 & + \Delta x(0) \left( \frac{\bar{z}_m}{h} h' v_g(-h)' + \overline{\min(h, -z_m)' v_g(-h)'} \right)
 \end{aligned}$$

190 In the general case of a non-monotonic topography (e.g. in the presence of ridges and is-  
 191 lands), the basin can be divided into a discrete number  $n > 1$  of subbasins of strictly monotonic  
 192 bathymetry. The above  $AMOC_{BCg}$  formulation remains valid for each subbasin of index  $i$ , with its  
 193 zonal boundaries being either closed by bathymetry or open above seamounts. The total  $AMOC_{BCg}$   
 194 transport becomes:

$$\begin{aligned}
 AMOC_{BCg} &= \sum_{i=1}^n \left( \frac{z_m g}{\rho_0 f} \int_{-h_b}^{z_m} \Delta \rho_i(z) dz + \frac{g}{\rho_0 f} \int_{z_m}^0 z \Delta \rho_i(z) dz \right) \\
 &= \frac{z_m g}{\rho_0 f} \int_{-h_b}^{z_m} \left( \sum_{z=-h(x_{Ei})} \rho(x_{Ei}, z) - \sum_{z=-h(x_{Wi})} \rho(x_{Wi}, z) \right) dz \\
 &\quad + \frac{g}{\rho_0 f} \int_{z_m}^0 z \left( \sum_{z=-h(x_{Ei})} \rho(x_{Ei}, z) - \sum_{z=-h(x_{Wi})} \rho(x_{Wi}, z) \right) dz
 \end{aligned}$$

195 where we have noted that densities at open boundaries cancel out, so that only bottom densities  
 196 (where  $z = -h(x_{Ei})$  and  $z = -h(x_{Wi})$ ) affect the  $AMOC_{BCg}$  transport. With a similar development  
 197 for the barotropic compensation of the net baroclinic flow, the  $AMOC_{BTg}$  becomes:

$$\begin{aligned}
 AMOC_{BTg} &= \frac{\bar{z}_m}{h} \left( AMOC_E + \frac{g}{\rho_0 f} \int_{-h_b}^0 z \left( \sum_{z=-h(x_{Ei})} \rho(x_{Ei}, z) - \sum_{z=-h(x_{Wi})} \rho(x_{Wi}, z) \right) dz \right) \\
 &\quad + AMOC_{g-EM}
 \end{aligned}$$

198 Finally, the AMOC reconstruction becomes:

$$\begin{aligned}
AMOC &= -\left(1 + \frac{\bar{z}_m}{h}\right) \frac{\Delta x(0)}{\rho_0 f} \bar{\tau}_x \\
&+ \frac{g}{\rho_0 f} \left( \int_{-h_b}^{z_m} \left( z_m + \frac{\bar{z}_m}{h} z \right) \left( \sum_{z=-h(x_{Ei})} \rho(x_{Ei}, z) - \sum_{z=-h(x_{Wi})} \rho(x_{Wi}, z) \right) dz \right. \\
&+ \left. \int_{z_m}^0 z \left( 1 + \frac{\bar{z}_m}{h} \right) \left( \sum_{z=-h(x_{Ei})} \rho(x_{Ei}, z) - \sum_{z=-h(x_{Wi})} \rho(x_{Wi}, z) \right) dz \right) \\
&+ \Delta x(0) \left( \frac{\bar{z}_m}{h} h' v_g(-h)' + \overline{\min(h, -z_m)}' v_g(-h)' \right)
\end{aligned}$$

199 It is almost identical to the single basin case, except that instead of evaluating the westernmost  
200 and easternmost density at each depth, all western and eastern boundary densities contribute to the  
201 geostrophic shear AMOC transport, their number depending on depth and latitude. We evaluate  
202 both AMOC reconstructions in SI6 to show that the single boundary definition gives an accurate  
203 approximation of the  $AMOC_{g-sh}$  transport in the CNRM-CM6 model.

### 204 **SI5: Alternative formulations of the external mode transport**

205 We demonstrate here that the external mode AMOC transport  $AMOC_{g-EM}$  of equation 19 is  
206 identical to the overturning contribution originated from bottom velocities of Baehr et al. (2004)  
207 (their equations 11 and 12) and to the external mode resulting from barotropic velocities of Hirschi  
208 and Marotzke (2007) (their equations 1 and 16).

209 The overturning contribution at the depth  $z_m$ ,  $\Psi_b(z_m)$ , originated by the bottom velocities, is  
210 defined by Baehr et al. (2004) as:

$$\begin{aligned}
\Psi_b(z_m) &= - \int_{-h_b}^{z_m} \int_{x_W(z)}^{x_E(z)} v_{corr}(-h) dx dz \\
&= + \int_{z_m}^0 \int_{x_W(z)}^{x_E(z)} v(-h) dx dz + \frac{\bar{z}_m}{h} \int_{-h_b}^0 \int_{x_W(z)}^{x_E(z)} v(-h) dx dz \\
&\simeq \int_{z_m}^0 \int_{x_W(z)}^{x_E(z)} v_g(-h) dx dz + \frac{\bar{z}_m}{h} \int_{-h_b}^0 \int_{x_W(z)}^{x_E(z)} v_g(-h) dx dz
\end{aligned}$$

211 where we have used the no net volumic flow condition in the first step, and we have assumed,  
 212 as it is implicitly done by Baehr et al. (2004), that bottom velocities are geostrophic in order to  
 213 reconstruct a geostrophic plus Ekman AMOC transport. The second term is the contribution of the  
 214 section-averaged bottom geostrophic velocities to the AMOC, which is cancelled out by the no net  
 215 volumic flow condition. Note that we have corrected an error of sign in equation 11 of Baehr et al.  
 216 (2004), and an error in the upper bound of vertical integration in their equation 12. Reverting the  
 217 order of integration and decomposing  $v_g(-h)$ ,  $h$  and  $\min(z_m, h)$  into their zonal mean and anomaly,  
 218 we obtain:

$$\begin{aligned}
 \Psi_b(z_m) &= \int_{x_W(0)}^{x_E(0)} \int_{\max(z_m, -h)}^0 v_g(-h) dx dz + \frac{\overline{z_m}}{\overline{h}} \int_{x_W(0)}^{x_E(0)} \int_{-h(x)}^0 v_g(-h) dx dz \\
 &= \int_{x_W(0)}^{x_E(0)} \int_{\min(h, -z_m)}^0 v_g(-h) dx + \frac{\overline{z_m}}{\overline{h}} \int_{x_W(0)}^{x_E(0)} h(x) v_g(-h) dx \\
 &= \int_{x_W(0)}^{x_E(0)} \min(h, -z_m) v_g(-h) dx - \frac{\overline{z_m}}{\overline{h}} \int_{x_W(0)}^{x_E(0)} h(x) v_g(-h) dx \\
 &= \Delta x(0) \left( -\overline{z_m v_g(-h)} + \overline{\min(h, -z_m)' v_g(-h)'} + \frac{\overline{z_m}}{\overline{h}} \left( \overline{h v_g(-h)} + \overline{h' v_g(-h)'} \right) \right) \\
 &= \Delta x(0) \left( \overline{\min(h, -z_m)' v_g(-h)'} + \frac{\overline{z_m}}{\overline{h}} \overline{h' v_g(-h)'} \right) \\
 &= AMOC_{g-EM}
 \end{aligned}$$

219 defining  $\overline{z_m} = -\overline{\min(h, -z_m)}$  as in SI2. The equivalence of both formulations means that the  
 220 external mode transport resulting from zonal covariances of  $v_g(-h)$  with bathymetry or the upper  
 221 limb depth is identical to the upper limb transport resulting from bottom velocities to which the  
 222 section averaged value has been removed to ensure no net volumic flow.

223 The external mode transport  $\Psi_{ex}$  of Hirschi and Marotzke (2007) (their equation 16) results  
 224 from barotropic velocities. Let us first reformulate the barotropic velocities  $v_{BT}$  of Hirschi and  
 225 Marotzke (2007). Under their decomposition of equation 16 (equivalent to our equation 19),  $v_{BT}$   
 226 is not the vertical mean velocity (their equation 1), because the shear velocity  $v_{sh}$  is expressed with

227 a zonally-integrated compensation (their equation 12) so that it "contain[s] a barotropic contribu-  
 228 tion" (Hirschi and Marotzke (2007), paragraph after their equation 14). As a consequence:

$$\begin{aligned}
 v_{BT} &= \langle v \rangle - \langle v_{sh} \rangle \\
 &= \langle v \rangle - \langle v_{BCg} \rangle + \frac{1}{\bar{h}\Delta x(0)} \int_{x_W}^{x_E} \int_{-h}^0 v_{BCg} dz dx
 \end{aligned}$$

229 with  $\langle \rangle$  the vertical averaging operator, and  $v_{BCg} = v_g - v_g(-h)$  the baroclinic geostrophic ve-  
 230 locities deduced from the thermal wind relation (identical to  $\tilde{v}$  of Hirschi and Marotzke (2007)).

231 We note that by definition:

$$\begin{aligned}
 \langle v \rangle &= \langle v_g(-h) \rangle + \langle v_{BCg} \rangle + \langle v_E \rangle \\
 &= v_g(-h) + \langle v_{BCg} \rangle + \frac{V_E}{h}
 \end{aligned}$$

232 with  $V_E$  the vertically-integrated Ekman transport. Therefore:

$$v_{BT} = v_g(-h) + \frac{1}{\bar{h}\Delta x(0)} \int_{x_W}^{x_E} \int_{-h}^0 v_{BCg} dz dx + \frac{V_E}{h}$$

233 Identically to our section SI4, the no net basin-scale flow constraint is:

$$\overline{v_g(-h)} = -\frac{1}{\bar{h}\Delta x(0)} \left( AMOC_E + \Delta x(0) \overline{h'v_g(-h)'} + \int_{x_W}^{x_E} \int_{-h}^0 v_{BCg} dz dx \right)$$

234 Finally, the external mode AMOC transport of Hirschi and Marotzke (2007) is:

$$\begin{aligned}
 \Psi_{ex} &= \int_{x_W}^{x_E} \int_{z_m}^0 v_{BT} dz dx \\
 &= -\frac{\bar{z}_m}{\bar{h}} \left( -\Delta x(0) \overline{v_g(-h)'} h' - \int_{x_W}^{x_E} \int_{-h}^0 v_{BCg} dz dx - AMOC_E \right) \\
 &\quad - \frac{\bar{z}_m}{\bar{h}} \left( \int_{x_W}^{x_E} \int_{-h}^0 v_{BCg} dz dx + AMOC_E \right) + \Delta x(0) \overline{v_g(-h)' \min(h, -z'_m)} \\
 &= \Delta x(0) \left( \frac{\bar{z}_m}{\bar{h}} \overline{h'v_g(-h)'} + \overline{\min(h, -z'_m)' v_g(-h)'} \right) \\
 &= AMOC_{g-EM}
 \end{aligned}$$

235 The contributions of Ekman and baroclinic geostrophic velocities to the external mode are can-  
236 celled by that of the barotropic geostrophic velocity due to the no net integral flow constraint. As  
237 a consequence, only zonal covariances of the latter with either bathymetry or the upper limb depth  
238 are a source of external mode transport, without causing any net integral flow.

## 239 **SI6: Sensitivity tests**

### 240 *Boundary definition*

241 We have proposed in section SI4 two AMOC reconstructions under variable topography, dif-  
242 fering only by the  $AMOC_{g-sh}$  transport formulation. The former considers a single western and  
243 eastern boundary, and the latter considers multiple western and eastern boundaries. The location  
244 and depth of boundaries are displayed in Fig.SI4a-b with a single boundary, and in Fig.SI4c-d  
245 with multiple boundaries. In the single boundary case, zonal boundaries are defined at each depth  
246 and latitude as the westernmost and easternmost oceanic grid cell. They are mostly located in  
247 the steep continental slopes near the coastline. Mid-oceanic ridges and the western flank of the  
248 Caribbean archipelago are mostly neglected, as a consequence of the strictly monotonic topogra-  
249 phy assumption. In the multiple boundary case, western (respectively eastern) boundaries are all  
250 oceanic grid cells neighbouring a continental grid cell to the west (respectively to the east). As  
251 a consequence, all but flat bottom grid cells are located at a zonal boundary. In particular, both  
252 flanks of mid-oceanic ridges and islands are included in this boundary definition. In both cases,  
253 the deepest bathymetry  $h_b$  is deduced at each latitude from the depth of the deepest boundary grid  
254 cell.

255 Fig.SI5 displays the Hovmoeller diagram of a) the total AMOC reconstruction and b) its  
256 geostrophic shear contribution as a function of latitude in the multiple boundary case. Similarly to  
257 the single boundary case, the AMOC reconstruction is able to capture the centennial AMOC cycle

258 of CNRM-CM6 both in terms of phase and amplitude. The similarity between both reconstructions  
259 shows the dominant role of westernmost and easternmost densities in setting the  $AMOC_{g-sh}$  vari-  
260 ability. Main differences between both definitions occur in the  $10 - 30^\circ N$  latitude band, suggesting  
261 some contribution of the Caribbean islands and Florida peninsula to the  $AMOC_{g-sh}$  variability. In  
262 the  $10 - 20^\circ N$  latitude band, the AMOC variability is improved and reduced with multiple bound-  
263 aries, whereas in the  $20 - 30^\circ N$  latitude band, it is noisier and partly out of phase with the total  
264 AMOC. This latter result is likely related to errors in the external mode transport reconstruction,  
265 as it largely dominates the AMOC at those latitudes (e.g. (McCarthy et al. 2015)). It could be  
266 related to the geostrophic assumption of bottom velocities, or numerical errors related to NEMO  
267 model's Arakawa-C grid.

268 Fig.SI6 displays the Talyor diagram of the AMOC reconstruction with a single boundary and  
269 multiple boundaries as a function of the total AMOC averaged over latitude bands (colored sym-  
270 bols) and its full meridional average over the  $30^\circ S - 60^\circ N$  latitude band excluding the Deep Trop-  
271 ics (black symbols). It confirms quantitatively the results found in the Hovmoeller diagram. Under  
272 either boundary definition, the AMOC reconstruction explains most of the AMOC variance at all  
273 latitude bands. The multiple boundary definition overperforms the single boundary one in terms of  
274 correlation at all latitude bands but between  $15 - 30^\circ N$ . Overall, the westernmost and easternmost  
275 boundary densities explain most of the low-frequency AMOC variability.

### 276 *Inclusion of the external mode*

277 The bottom currents map (Fig.2c) suggests that the external mode plays a significant role in the  
278 total AMOC at western boundaries and in subpolar latitudes. We diagnose here the added value  
279 of including it to the AMOC reconstruction. Fig.SI6 evaluates in a Taylor diagram the single  
280 boundary AMOC reconstruction with (circles) and without (lower triangle) the external mode

281 contribution. There is no clear added value of including the external mode to the reconstruction  
282 of the multidecadal AMOC variability. Indeed, at all latitude bands, the AMOC reconstruction  
283 without the external mode explains over 80% of the AMOC variance ( $r > 0.9$ ), with a normalized  
284 standard deviation within 30% of unity and a normalized root mean squared error below 0.5.  
285 Including the external mode marginally improves the normalized standard deviation and reduces  
286 the error of the meridional average, but this results from compensation between latitude bands  
287 as the improvement is overall not evident. We conclude that the inclusion of the external mode  
288 is physically motivated but it contributes marginally to the AMOC low-frequency variability in  
289 CNRM-CM6.

## LIST OF FIGURES

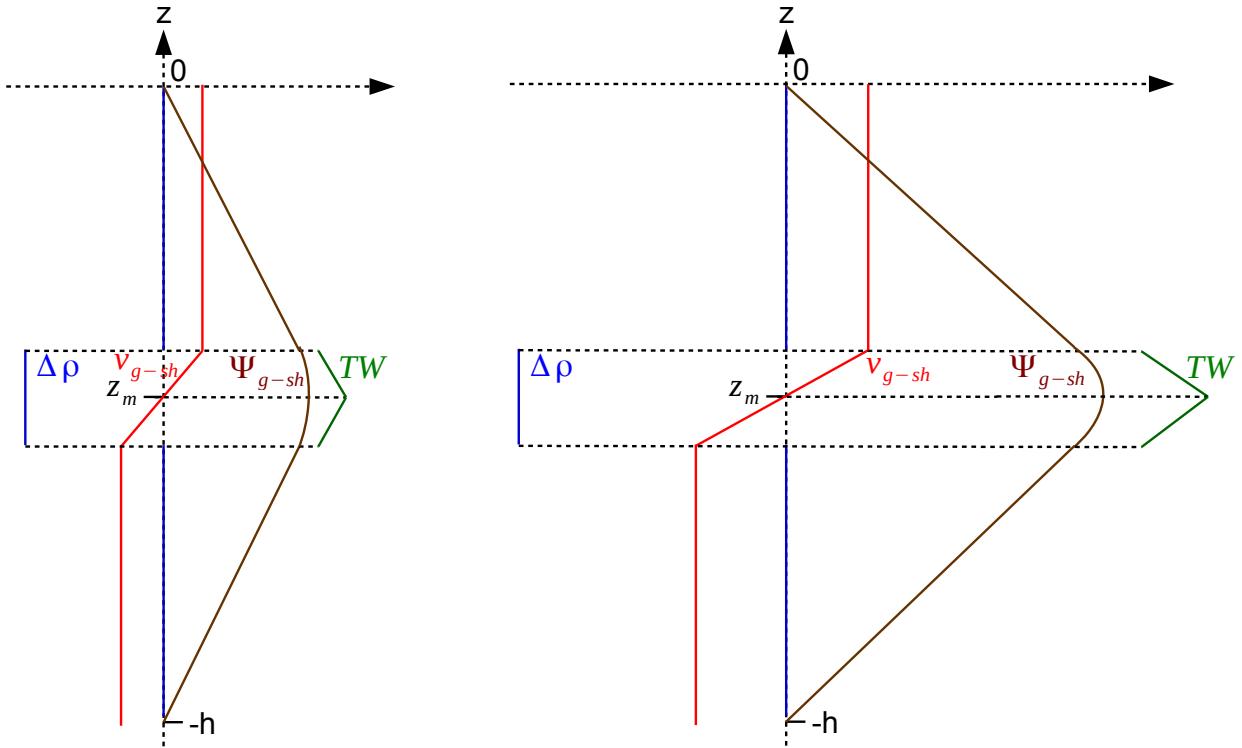

- 328 **Fig. 1.** a) Average residual Atlantic meridional overturning stream function ( $\Psi_r/\rho_0$  in Sv, with  
329  $\rho_0 = 1025\text{kg}/\text{m}^3$ ) in CNRM-CM6.  $\Psi_r$  represents the residual mean mass transport (in  $\text{kg}/\text{s}$ )  
330 that includes the Eulerian mean circulation plus the parametrized eddy-driven mass over-  
331 turning. The dashed black line shows the depth  $z_m = -997\text{m}$  of maximum overturning. b)  
332 (top) Atlantic Meridional Overturning Circulation deduced as the depth-maximum Eulerian  
333 mean ( $AMOC$ , black) and residual mean ( $AMOC_r$ , blue) stream function, and (bottom) their  
334 interannual correlation ( $r(AMOC_r, AMOC)$ ) in CNRM-CM6. . . . . 23
- 335 **Fig. 2.** Control of the maximum overturning depth  $z_m$  by the density anomaly profile  $\Delta\rho(z)$ . Two  
336 vertically-symmetric cases are shown to illustrate how the depth where  $\Delta\rho(z)$  (blue) occurs  
337 controls the vertical profile of the sheared geostrophic velocities ( $v_{g-sh}$ , red), their over-  
338 turning stream function ( $\Psi_{g-sh}$ , brown), the value of  $z_m$  and ultimately the thermal wind  
339 transport ( $TW$ , green). For illustrative purposes, we assume that the overturning is entirely  
340 determined by sheared geostrophic velocities  $v_{g-sh}$ . . . . . 24
- 341 **Fig. 3.** Control of the thermal wind transport  $TW$  by the magnitude of density anomalies. Two  
342 cases are shown to illustrate that for a given maximum overturning depth  $z_m$ , the thermal  
343 wind transport  $TW$  (green) at a given depth is proportional to the magnitude of the den-  
344 sity anomaly  $\Delta\rho$  (blue). Sheared geostrophic velocities ( $v_{g-sh}$ , red) and their overturning  
345 stream function ( $\Psi_{g-sh}$ , brown) are also shown. For illustrative purposes, we assume that  
346 the overturning is entirely determined by sheared geostrophic velocities  $v_{g-sh}$ . . . . . 25
- 347 **Fig. 4.** Depth of zonal boundaries used for the geostrophic shear transport reconstruction  
348  $AMOC_{g-sh}$  (shades) in the a) single and b) multiple boundary case. Bathymetric contours  
349 are displayed in black. . . . . 26
- 350 **Fig. 5.** Hovmoeller diagram of the 25-year average a) AMOC reconstruction anomaly ( $AMOC_E +$   
351  $AMOC_g$ ) and b) its geostrophic shear component ( $AMOC_{g-sh}$ ) when considering multiple  
352 western and eastern boundaries at each latitude and depth. . . . . 27
- 353 **Fig. 6.** a) Taylor diagram of the 25-year average AMOC reconstruction with single boundary (cir-  
354 cles), multiple boundaries (diamonds), and with a single boundary when excluding the ex-  
355 ternal mode (lower triangle), as a function of the total AMOC (star). Colors indicate the  
356 latitude ( $15^\circ$  average), with black symbols the full meridional average over the  $30^\circ S - 60^\circ N$   
357 latitude band excluding the Deep Tropics (black symbols). . . . . 28

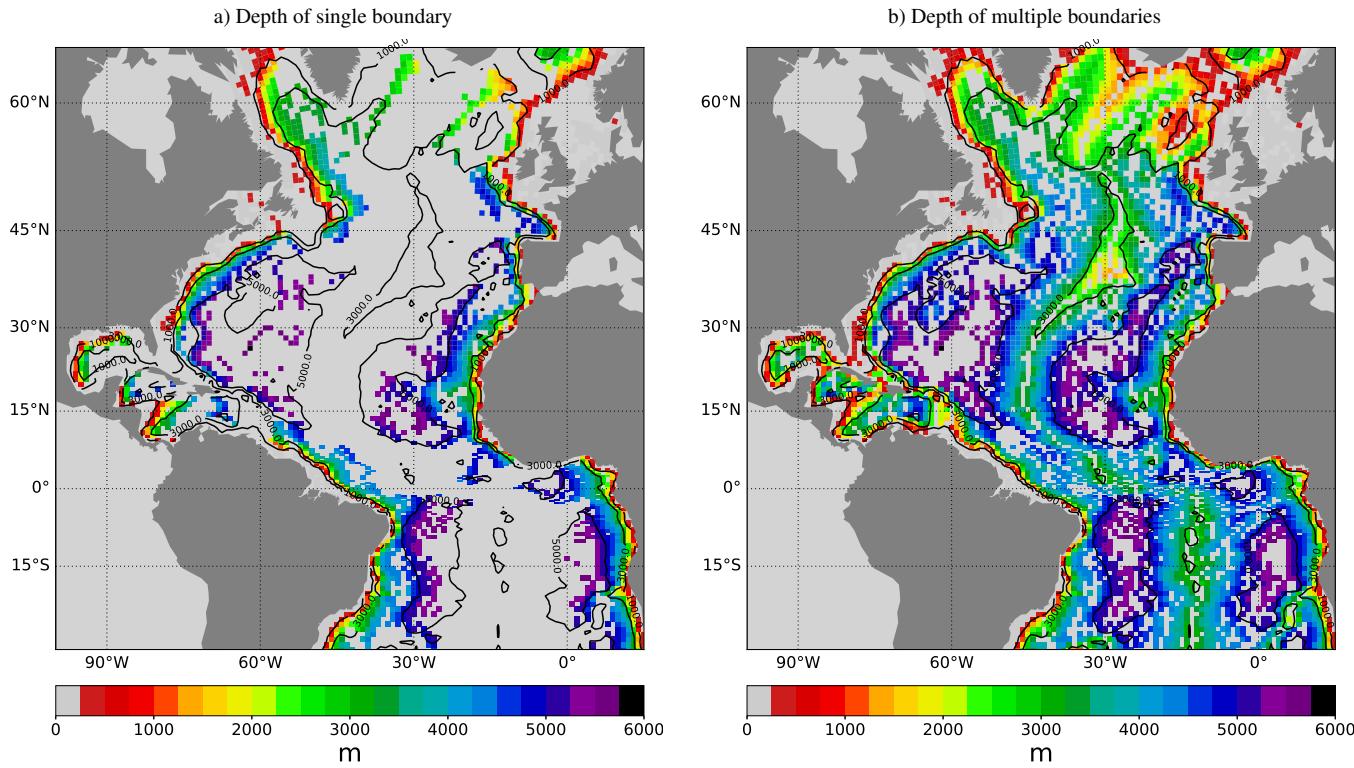

358 Figure SI 1. a) Average residual Atlantic meridional overturning stream function ( $\Psi_r/\rho_0$  in Sv, with  $\rho_0 =$   
 359  $1025\text{kg}/\text{m}^3$ ) in CNRM-CM6.  $\Psi_r$  represents the residual mean mass transport (in  $\text{kg}/\text{s}$ ) that includes the Eulerian  
 360 mean circulation plus the parametrized eddy-driven mass overturning. The dashed black line shows the depth  
 361  $z_m = -997\text{m}$  of maximum overturning. b) (top) Atlantic Meridional Overturning Circulation deduced as the  
 362 depth-maximum Eulerian mean ( $AMOC$ , black) and residual mean ( $AMOC_r$ , blue) stream function, and (bottom)  
 363 their interannual correlation ( $r(AMOC_r, AMOC)$ ) in CNRM-CM6.

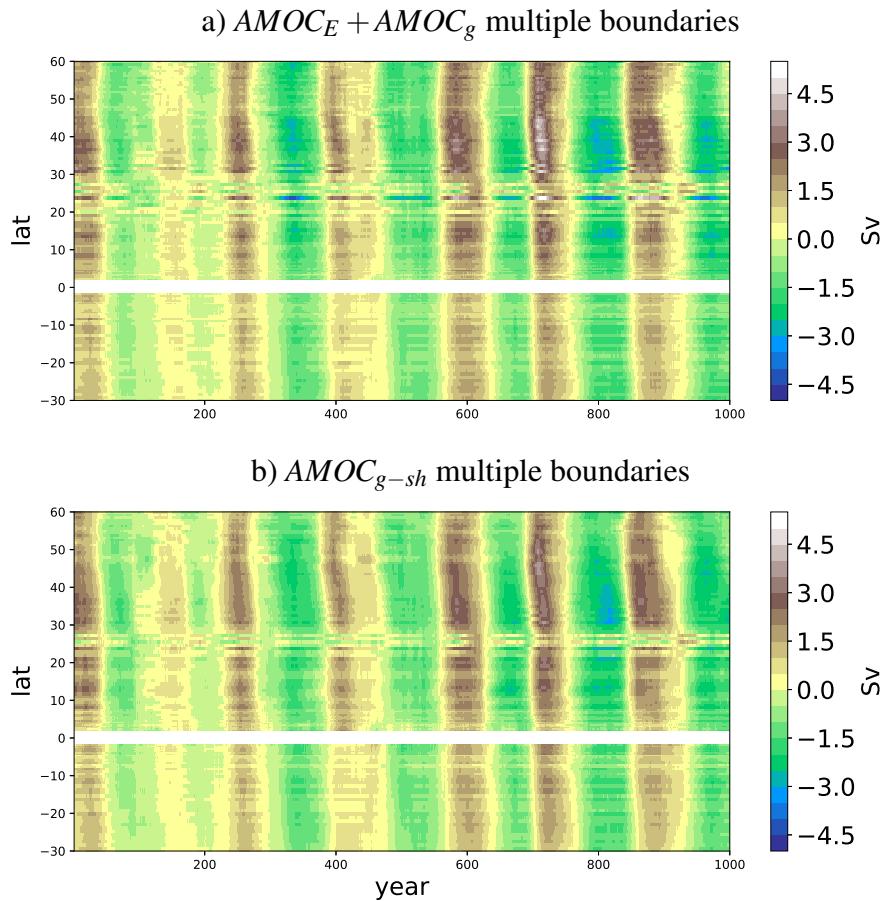

364 Figure SI 2. Control of the maximum overturning depth  $z_m$  by the density anomaly profile  $\Delta\rho(z)$ . Two  
 365 vertically-symmetric cases are shown to illustrate how the depth where  $\Delta\rho(z)$  (blue) occurs controls the vertical  
 366 profile of the sheared geostrophic velocities ( $v_{g-sh}$ , red), their overturning stream function ( $\Psi_{g-sh}$ , brown), the  
 367 value of  $z_m$  and ultimately the thermal wind transport ( $TW$ , green). For illustrative purposes, we assume that the  
 368 overturning is entirely determined by sheared geostrophic velocities  $v_{g-sh}$ .

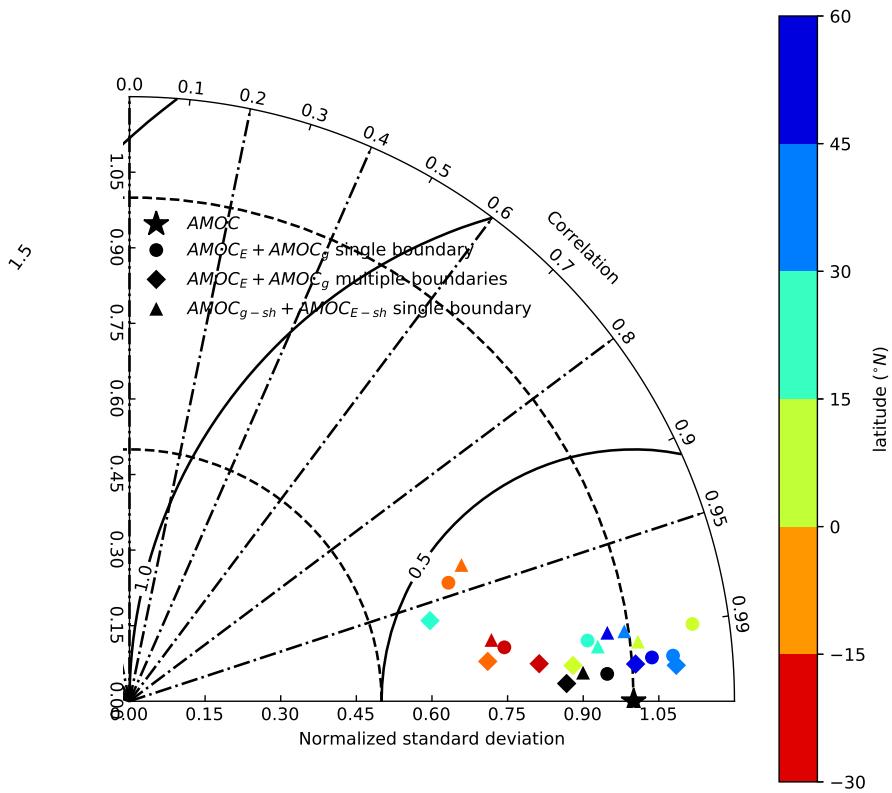

369 Figure SI 3. Control of the thermal wind transport  $TW$  by the magnitude of density anomalies. Two cases are  
 370 shown to illustrate that for a given maximum overturning depth  $z_m$ , the thermal wind transport  $TW$  (green) at a  
 371 given depth is proportional to the magnitude of the density anomaly  $\Delta\rho$  (blue). Sheared geostrophic velocities  
 372 ( $v_{g-sh}$ , red) and their overturning stream function ( $\Psi_{g-sh}$ , brown) are also shown. For illustrative purposes, we  
 373 assume that the overturning is entirely determined by sheared geostrophic velocities  $v_{g-sh}$ .

374 Figure SI 4. Depth of zonal boundaries used for the geostrophic shear transport reconstruction  $AMOC_{g-sh}$   
 375 (shades) in the a) single and b) multiple boundary case. Bathymetric contours are displayed in black.

376 Figure SI 5. Hovmoeller diagram of the 25-year average a) AMOC reconstruction anomaly ( $AMOC_E +$   
 377  $AMOC_g$ ) and b) its geostrophic shear component ( $AMOC_{g-sh}$ ) when considering multiple western and eastern  
 378 boundaries at each latitude and depth.

379 Figure SI 6. a) Taylor diagram of the 25-year average AMOC reconstruction with single boundary (circles),  
 380 multiple boundaries (diamonds), and with a single boundary when excluding the external mode (lower triangle),  
 381 as a function of the total AMOC (star). Colors indicate the latitude (15° average), with black symbols the full  
 382 meridional average over the 30°S – 60°N latitude band excluding the Deep Tropics (black symbols).
